

## Setting up Jupyter on your own server

Nimi: Petri Salminen  
Opnum: 243840  
Email: petri.salminen@tuni.fi

So you got your server up and running and you would like to have a way to run Jupyter?

### Installation

Install necessary Python packages: `sudo apt install python3-pip python3-dev`

Make sure that Pip is up-to-date: `sudo -H pip3 install --upgrade pip`

Install virtualenv: `sudo -H pip3 install virtualenv`

Make a directory for the jupyter and cd in there: `mkdir jupyter && cd jupyter`

Generate the virtualenv: `virtualenv jupyter_env`

Activate the virtualenv: `source jupyter_env/bin/activate`

Install jupyter: `pip install jupyter`

### Configuration

Generate jupyter-stuff: `jupyter notebook --generate-config`

Generate password: `jupyter notebook password`

Start the jupyter: `jupyter notebook`

Set up ssh tunnel from your LOCAL machine with: `ssh -N -L 8888:localhost:8888 petri@remote.com` This just maps your traffic trying to get to `localhost:8888` to `remote.com` using SSH.

Then access `http://localhost:8888` . Now you can enjoy your fresh jupyter server! Or can you....?

### Problems emerge

However, the jupyter is unable to connect to python kernel, so running any code is kind of hard. This is actually a problem on the server. There were 404 (Not found) and 405 (Method not allowed) for GET calls to `/api/kernels/kernelhash/channels?session_id=sessionhash` . For some reason (could be firewall, for example) the GET was not responded correctly.

This was solved by adding a configuration block to nginx (web server), which would allow the requests and the use of websockets. The config can be found from <https://github.com/jupyter/notebook/issues/2664#issuecomment-346249652> (<https://github.com/jupyter/notebook/issues/2664#issuecomment-346249652>)

## What next?

I will probably want to make the jupyter work with my domain HTTPS instead of clunky SSH tunnel. With a strong password this should not introduce too much security issues.

## Update

I managed to get the HTTPS working! [https://jupyter-notebook.readthedocs.io/en/stable/public\\_server.html#notebook-public-server](https://jupyter-notebook.readthedocs.io/en/stable/public_server.html#notebook-public-server) ([https://jupyter-notebook.readthedocs.io/en/stable/public\\_server.html#notebook-public-server](https://jupyter-notebook.readthedocs.io/en/stable/public_server.html#notebook-public-server)) helped a lot and <http://www.albertauyeung.com/post/setup-jupyter-nginx-supervisor/> (<http://www.albertauyeung.com/post/setup-jupyter-nginx-supervisor/>) was nice too.

I stumbled across a problem where I got [W 10:33:45.605 NotebookApp] SSL Error on 8 ('127.0.0.1', 33996): [SSL: HTTP\_REQUEST] http request (\_ssl.c:847) from the Jupyter server. This was resolved by adding http-> https to the proxy\_pass clause in nginx config.

The notebook is available (behind a password) in <https://salminen.dev/notebook> (<https://salminen.dev/notebook>)
